

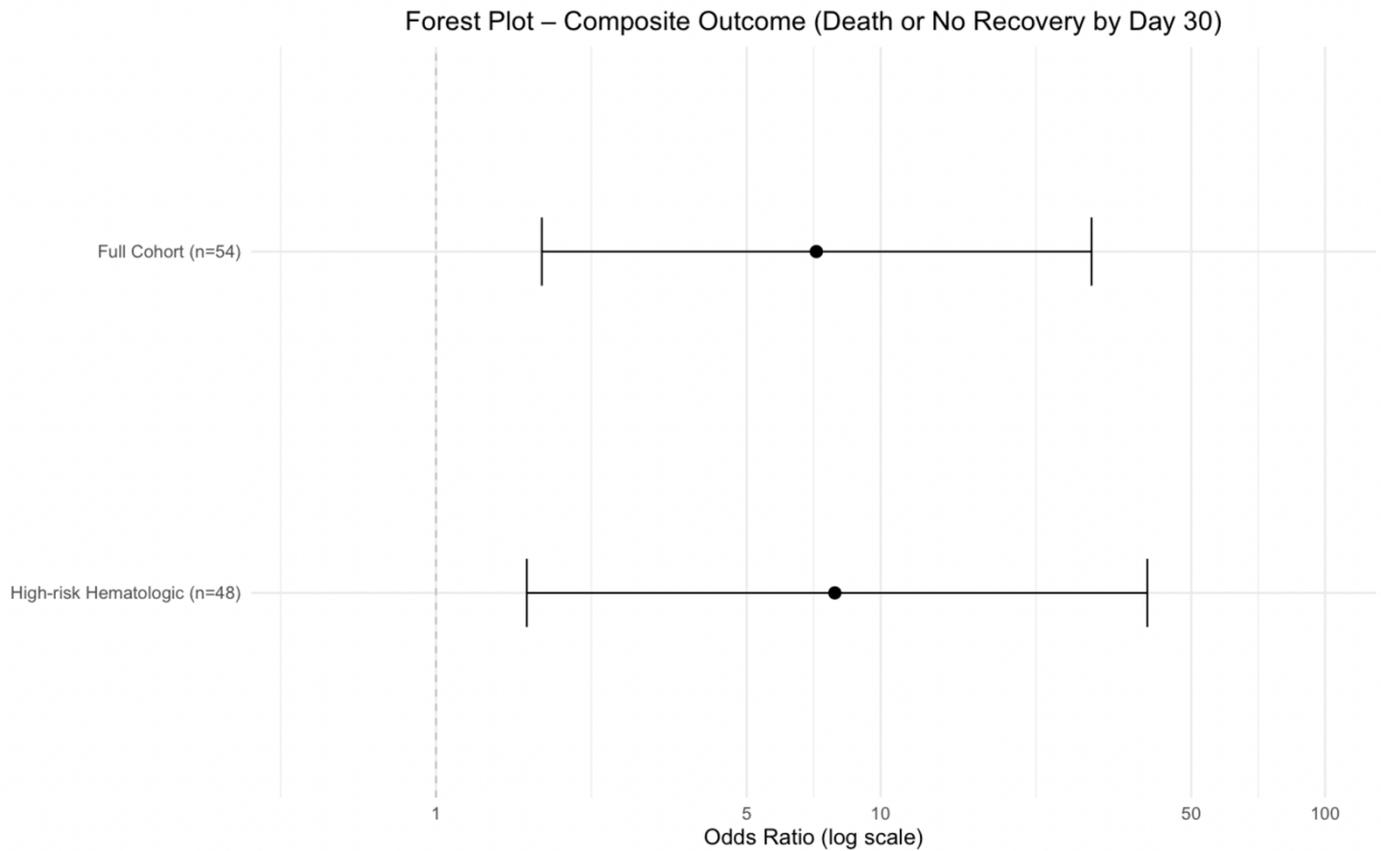

Figure S6. Forest plot of composite outcome (death or no recovery by day 30)

Forest plot illustrating the association between granulocyte transfusion (GT) and the composite outcome of death or no clinical recovery by Day 30 in both the full cohort (n = 54) and the high-risk hematologic disorder subgroup (n = 48). Adjusted odds ratios (OR) and 95% confidence intervals (CI) were derived from multivariate logistic regression models controlling for fungal infection, multidrug resistant (MDR) bacterial infection, and disease status or baseline ANC. GT was significantly associated with a lower risk of poor composite outcome in both analyses. The dotted vertical line at OR = 1.0 indicates the null effect.
